Goal: place text into a pre-defined categories, e.g.,

- Topics or issues, e.g., policy areas for legislation
- Source or authors, e.g., stylometry
- Spam or other filters (e.g., sexually explicit content)
- Sentiment or ratings, e.g., negative/positive

Approaches:

- Dictionaries: pre-identified words that associate with classes are counted/weighted
- **Supervised classification**: statistical models identify separating words

The goal is to classify every document into one category:

- $i$  documents, ( $i = 1, \dots, N$ ) with  $j$  features:  
 $x_i = (x_{1i}, x_{2i}, \dots, x_{ji})$
- $k$  categories, ( $k = 1, \dots, K$ ) such that  $\{C_1, C_2, \dots, C_K\}$
- Labeled documents,  $Y = (Y_1, Y_2, \dots, Y_{N_{train}})$  such that  
 $Y_i \in \{C_1, C_2, \dots, C_K\}$

Generally, we'll define some objective function  $y = f(X, \theta)$   
where  $\theta = (\theta_1, \theta_2, \dots, \theta_N)$  are feature weights.

- Human coders classify a subset,  $N_{train}$  documents, into predetermined categories (or text is conveniently pre-coded).
  - Need clear categories, simple coding rules, and trained coders. This is hard!
  - Use multiple coders for (at least some) documents to test inter-coder reliability (e.g., Krippendorff's  $\alpha$ , Cohen's  $\kappa$ ).
  - Produce a labeled set for training, a labeled set for validation. How many?
- Labeled documents are used to train a model. Optimize with respect to  $\theta$  to “learn” the weights.
- Model is validated against another hand-labeled subset,  $N_{test}$ . Obtain predicted fit for new data  $f(X_i, \hat{\theta})$  and compare to known categories.
- Chosen model is applied to unlabeled cases.

# Naive Bayes Classifier

For each document  $i$ , we want to infer the most likely category  $C_k$ , based on features of the document  $x_i$

$$C_{Max} = \arg \max_k p(C_k|x_i)$$

Use Bayes' rule to estimate  $p(C_k|x_i)$ .

$$\begin{aligned} p(C_k|x_i) &= \frac{p(C_k, x_i)}{p(x_i)} \\ &= \frac{p(C_k)p(x_i|C_k)}{p(x_i)} \end{aligned}$$

A simple application of Bayes' rule; often surprisingly useful.  
For each document  $i$ , we want to infer the most likely category  $C_k$ , based on features of the document  $x_i$

$$C_{Max} = \arg \max_k p(C_k|x_i)$$

Use Bayes' rule to estimate  $p(C_k|x_i)$ .

$$\begin{aligned} p(C_k|x_i) &= \frac{p(C_k, x_i)}{p(x_i)} \\ &= \frac{p(C_k)p(x_i|C_k)}{p(x_i)} \end{aligned}$$

Two probabilities to estimate

- $P(C_k) = \frac{\# \text{ docs in } k}{\# \text{ docs in } N_{train}}$
- $P(x_i|C_k)$

The second is complicated unless we make the simplifying assumption: features,  $x_i$ , are independent. Ergo... “naive”

# Naive Bayes Classifier

$$p(x_i|C_k) = \prod_{j=1}^J p(x_{ij}|C_k)$$

This is what we're maximizing. Classification is made using maximum a posteriori (MAP) decision rule.

For any given feature of a document  $z$ , we have

$$P(x_{im} = z|C_k) = \frac{\#(x_{im} = w \text{ and } C = C_k)}{\#(C = C_k)}$$

What happens when a word-category combination doesn't appear in the training data? This is zero!

# Naive Bayes Classifier

$$p(x_i|C_k) = \prod_{j=1}^J p(x_{ij}|C_k)$$

This is what we're maximizing. Classification is made using maximum a posteriori (MAP) decision rule.

For any given feature of a document  $z$ , we have

$$P(x_{im} = z|C_k) = \frac{\#(x_{im} = w \text{ and } C = C_k)}{\#(C = C_k)}$$

What happens when a word-category combination doesn't appear in the training data? This is zero! To eliminate zeroes, smooth the estimate, e.g., Laplace smoothing, adds one to each count

$$P(x_{im} = z|C_k) = \frac{\#(x_{im} = w \text{ and } C = C_k) + 1}{\#(C = C_k)}$$

## Logistic regression

- Like standard linear regression, but for binary outcomes
- Rather than predict outcome,  $y$ , predict  $p(y = 1)$
- Because probabilities are bounded, use a cumulative probability distribution – an S-shaped curve
- Select a threshold to map probabilities into binary outcome, e.g.,  $p > .5 = 1$  and  $p < .5 = 0$

- Because probabilities are bounded, use a cumulative probability distribution – an S-shaped curve
- Select a threshold to map probabilities into binary outcome, e.g.,  $p > .5 = 1$  and  $p < .5 = 0$

## Regularization

- Lots of features,  $p \gg n$  problem; and features are highly correlated
- Leads to more variable estimates and overfitting
- Regularization constrains the coefficient estimates, shrinks them towards zero

## The Lasso

- Uses all predictors, shrinks less important ones to 0
- Adds a tuning paramter,  $\lambda$ , as penalty to model complexity
- When  $\lambda = 0$  Lasso produces least-squares/MLE fit; as  $\lambda \rightarrow \infty$  all coefficients approach zero

# Logit with Lasso Regularization

- Adds a tuning paramter,  $\lambda$ , as penalty to model complexity
- When  $\lambda = 0$  Lasso produces least-squares/MLE fit; as  $\lambda \rightarrow \infty$  all coefficients approach zero

## N-fold cross-validation to choose $\lambda$

- Split data into  $N$  sets
- Use  $N - 1$  sets to build model and omitted set to validate
- Repeat for all  $N$  sets
- Average the misclassification rate

Do this for a range of  $\lambda$  and choose  $\lambda$  with lowest average misclassification

- The  $C$  parameter adds a penalty for misclassification, balancing misclassification and maximization of the hyperplane. We minimize

$$\|\omega\|^2 + C \sum_{i=1}^n \xi$$

- The kernel function extends the algorithm to patterns that are not linearly separable by mapping the original data into a higher dimensional space, e.g.,

$$K(x, y) = (x \cdot y + 1)^p \quad \textit{polynomial}$$

$$K(x, y) = \exp\left(-\frac{\|x - y\|^2}{2\sigma^2}\right) \quad \textit{radial}$$

$$K(x, y) = \tanh(\kappa x \cdot y - \delta) \quad \textit{sigmoid}$$

RTextTools implements nine algorithms (there are many more possibilities), including

- Maximum entropy (MAXENT, from `maxent`)
- Classification trees (TREE, from `tree`)
- Random forests (RF, from `randomForest`)
- Bootstrap aggregation (BAGGING, from `ipred`)
- Linear discriminant analysis (SLDA; from `ipred`)
- Logit boost classifier (BOOSTING, from `caTools`)
- Neural net (NNET, from `nnet`)

And ensemble approaches: bagging, boosting, stacking...
